#### Abstract

Like most other states, Missouri uses assessments intended to measure whether students are on a pathway to "college and career readiness." The state longitudinal data system now has the capacity to directly test that claim. We make use of $8^{\text {th }}$-grade assessment (MAP) scores in Math, Science, and Communication Arts for roughly 260,000 first-time Missouri freshmen who began high school between Fall, 2009 and Fall, 2012. These students were tracked through high school and for five years following on-time high school graduation. We find a strong positive association between MAP performance scores in $8^{\text {th }}$ grade Math, Science, and Communication Arts and post-secondary college attendance and degree completion. This is true overall and for White, Black, and Hispanic students disaggregated by gender. Proficiency on all three exams matters even more. Based on a logistic forecasting model, if all students who scored below Proficient on the $8^{\text {th }}$-grade MAP raised their scores to Proficient, the number earning postsecondary degrees would increase by roughly 50 percent. Black and Hispanic students earning post-secondary degrees would increase by roughly 150 and 75 percent, respectively. We conclude that $8^{\text {th }}$-grade MAP proficiency scores are highly informative about whether students are on a pathway to college and career readiness.

## 1. Introduction

The higher stakes federal consequences of the No Child Left Behind Act (NCLB) have given way to weaker nudges in the 2015 Every Student Succeeds Act (ESSA). Nonetheless, ESSA requires that all states have accountability systems that make use of early grade assessments in English, Math, and Science intended to measure student progress toward "college and career readiness" (Every Student Succeeds Act, 2015).

A substantial literature has examined the relationship between measures of high school academic achievement and economic mobility. ${ }^{1}$ However, few papers have examined the link between NCLB grade 3-8 state assessments in state longitudinal data systems (SLDS) and postsecondary achievement. Some have used state assessment data to identify "at risk" students (e.g., Li, et.al., 2017; Fazlul, Koedel, Parsons, 2022). However, rather than using a SLDS to identify downside risk, in the paper we use it to identify the association between $8^{\text {th }}$ grade performance and later college achievement. This is similar in spirit to Austin, et.al. (2023), who examine academic mobility of students in grades K-12 in seven states (including Missouri). However, in our case, we examine the relationship between student performance levels on all three $8^{\text {th }}$-grade state assessments (Missouri Assessment of Progress, or MAP) and subsequent educational attainment for Missouri public school students.

Performance levels are the typical way that state assessment results are reported to students, parents, school staff and the general public. They are also the measures that enter state accountability systems. This is the case with MAP as well. Based on their reported scale scores

[^0]students are placed into one of four performance levels - Below Basic, Basic, Proficient, or Advanced - all intended to track the "college and career readiness" of the student. ${ }^{2}$

These cutoffs are set by panel members who make judgements regarding the appropriate cuts for the various levels. They base these on the state standards for the subject and grade, and their own experience and knowledge of the field. They are also informed by data on the distribution of scores for current test-takers. Although the intent of the exercise is to assess progress toward "college and career readiness," these panel members are making informed guesses as to how student performance on these assessments will translate into post-secondary outcomes such as college attendance and degree completion many years in the future. However, with the development of State Longitudinal Data Systems (SLDS), heavily subsidized by the U.S. Department of Education, state policymakers can now assess the relationship between performance on state assessments and post-secondary education attainment.

Missouri's SLDS, first implemented in 2006, now makes it possible to track multiple cohorts of students through the public K-12 system and into post-secondary education and training. This permits researchers to empirically examine the relationship between students' performance on the $8^{\text {th }}$-grade standardized assessment and post-secondary education achievement.

This paper contributes to the research literature on NCLB by examining the long-run association between the performance levels on pre-high school assessments, in the form these are

[^1]reported to parents and to the general public and which inform the state accountability system, and post-secondary educational attainment. We find strong positive relationships between performance and educational attainment in the overall population and for race-by-gender groups. Given the strength of these relationships, we estimate a statistical model that predicts postsecondary educational attainment based on $8^{\text {th }}$-grade performance scores on all of the NCLB tested areas (i.e., Communication Arts, Math, Science). We use the model to simulate the effect of reaching the NCLB target of moving all students who score below Proficient to Proficient on all of the assessments. The model forecasts large increases in post-secondary degree attainment in the overall population, driven by very large increases for Black and Hispanic students.

## 2. Data

The data for this study comes from the State Longitudinal Data System (SLDS) maintained by the Missouri Department of Elementary and Secondary Education (DESE). We use four cohorts of first-time $9^{\text {th }}$-grade students who began public high school in Fall 2009 - Fall 2012. There are approximately 70,000 students per cohort attending 545 public high schools. The analytic population is restricted to White, Black, and Hispanic students. The three racial/ethnic groups constitute $96.1 \%$ of the total first-time $9^{\text {th }}$-grade students yielding a total sample size of 264,590 students. The racial/ethnic composition of the analytic population is $78.2 \%$ White, 17.5\% Black, and 4.3\% Hispanic.

We examine three post-secondary outcomes plus high school graduation. High school graduation information uses the SLDA data. The post-secondary outcomes make use of a link between DESE SLDS student records and data from the National Student Clearinghouse (NCS). The NCS tracks student enrollment by semester and covers 97 percent of public and private higher education institutions across the country. Missouri high school student data are linked to five years of the NSC data following expected on-time high school graduation. NSC data
provides information on college enrollment (e.g., start and end date, full-time or half-time status, majors), institution types (e.g., two-year vs four-year and private vs public), and degree completion. Note that the NSC data includes post-secondary enrollment in Missouri as well as out-of-state institutions. ${ }^{3}$

## 3. 8th Grade MAP Performance Levels

Missouri $8^{\text {th }}$ graders took three state assessments: Math, Science, and Communication Arts. ${ }^{4}$ As noted above, based on test performance, students are placed into one of four performance levels, ranked low to high: Below Basic, Basic, Proficient and Advanced.

Figure 1 reports the overall distribution of students in our student population by the four performance levels on the three assessments. The distribution of students varies across the three assessments. For example, 14.8 and 16.2 percent of students score Below Basic on the Math and Science exams, respectively. However, only 4.6 percent score in this bottom category in Communication Arts. Overall, the Science exam seems to be the toughest, with relatively fewer students scoring Advanced and more scoring Below Basic. Figure 2 shows a wide disparity in test performance across the eight race and gender groups considered in this study. White female students receive the highest scores on Communication Arts and White male students score highest on Math and Science. Black male students have the largest share of Below Basic scores on all of the assessments. Hispanic students of either gender generally fall between Black and White students in performance.

## 4. 8th Grade MAP Performance and Educational Attainment

In Figure 3 we show the relationship between these $8^{\text {th }}$-grade MAP scores and educational attainment. For each exam, we show the share of students at each MAP performance

[^2]level who reach the education attainment milestone. The association is positive for all of the exams and educational milestones. The strength of the association is stronger for higher levels of education attainment. For example, the share of Math Below Basic students who attend college is .189 versus .74 for Advanced - a ratio of 3.9. The share of Math Below Basic students who earn a four-year degree is .015 versus .445 for Advanced - a ratio of 29.7.

The previous calculations illustrate one way to characterize the strength of the association between MAP performance levels and educational outcomes. These are called odds ratios, and are simply the ratio of probabilities of a given educational outcome for students in a higher and lower $8^{\text {th }}$-grade performance level on a given MAP exam. In Figure 4, we report the odds ratios for various levels of educational attainment for a student scoring Advanced versus a student scoring Below Basic on the MAP exams. For example, as compared to a Below Basic student, a student scoring Advanced on the $8^{\text {th }}$ grade Math MAP exam is 1.4 times as more likely to graduate from high school, 3.9 times more likely to attend college, 13.5 times more likely to earn a post-secondary degree, and 29.7 times more likely to earn a four-year degree. While higher scores on all three exams are associated with improved odds of educational attainment, the Communication Arts exam has the strongest positive association. For example, the Advanced to Below Basic odds ratio for earning a four-year college degree is 29.7 for the Math exam but 61.6 for the Communication Arts exam. ${ }^{5}$

## 5. MAP Scores and Educational Attainment by Race/Ethnicity and Gender

In the previous section, we found a strong association between $8^{\text {th }}$-grade MAP scores and subsequent educational attainment. In this section, we examine whether this association holds for

[^3]race and gender groups. As noted in the Data section, our analytic population includes all students identified as White, Black or Hispanic in the SLDS data system (96 percent of Missouri public school enrollment). In this analysis, students are classified into six groups: White, Black, and Hispanic by gender. We will consider the same four educational attainment outcomes: high school graduation, college attendance, degree completion (any), and four-year degree completion. Hence, we have 24 relationships (four outcomes by six groups) to examine. Figures 5-7 report results for each of the three MAP exams. The same strong positive relationship between the performance levels and educational attainment observed in the overall population is also found for each of the six groups.

Figure 8 provides simple summary measures of the association between educational attainment and MAP performance measures by race/ethnicity and gender. Here we report the odds ratio of various outcomes for students who score Proficient versus Basic on the $8^{\text {th }}$-grade exam. We see that the association is very strong within all of the six groups. The odds of earning a post-secondary degree roughly double for a student who moves from Basic to Proficient on any of the exams. The odds of earning a four-year degree roughly triple for the same achievement gain. ${ }^{6}$

## 6. Moving All Students to Proficiency in 8th Grade

The goal of federal legislation such as No Child Left Behind (NCLB) and the Every Student Succeeds Act (ESSA) is to raise the performance of all students to at least Proficient on their state assessment. This is the aim of state accountability systems as well. The SLDS data allow us to simulate the effect of 100 percent proficiency on educational attainment. In order to do this, we estimate a simple logit probability model for the various educational attainment

[^4]outcomes we have considered (e.g., college attendance, degree completion). The model is estimated at the student level, where the attainment outcome for student $i\left(Y_{i}\right)$ is specified as a function of the performance levels of the $8^{\text {th }}$ grade MAP assessment in three subjects. Vectors of categorical indicators for performance levels and the FRL indicator are entered in the following statistical model, and this is estimated separately for each of the six groups:
$$
\operatorname{logit}\left(Y_{i}\right)=\ln \left(\frac{P\left(Y_{i}=1\right)}{1-P\left(Y_{i}=1\right)}\right)=\beta_{0}+\beta_{1} M a t h P L_{i}+\beta_{2} \text { SciencePL }_{i}+\beta_{3} C A P L_{i}+\beta_{4} F R L
$$

Consistent with the graphical analysis discussed in the previous section, we find large, significant positive effects of each exam on educational outcomes. In addition, the model overall demonstrates good performance in predicting educational attainment for individuals and for each subgroup. Concordance rates rise from 75 percent for college attendance, to 80 and 82 percent for any degree completion and four-year degree completion. Details are presented in the Statistical Appendix.

We used the estimated coefficients from the probability model to examine the following scenario. We simulate the increase in overall educational attainment if all students who currently score Below Basic and Basic raised their scores to Proficient. Figure 9 presents the results at the population level and for each of the race/ethnicity by gender groups.

Two points are worth noting. First, increases in educational attainment are much larger as a result of raising the performance level for all three assessments rather than a single assessment, hence the much larger proportionate impacts in these as compared to the earlier figures. Second, these effects are much more pronounced for Hispanic students, and especially Black students, as compared to White students, because the boost to 100 percent Proficient and above is proportionately much larger given their lower initial starting point (Figure 2).

Figure 9 reports results on two levels of post-secondary degree attainment: any degree and four-year degree. If all students who are below Proficient reached Proficient our estimate is that the number students earning a post-secondary degree would grow by 52.2 percent. Students earning a four-year degree would grow by 55.4 percent. The range of impacts among the groups, however, is very large. Focusing on the any degree results, the gains for White male students and female students are 37.5 and 41.7 percent respectively. For Black female and male students the corresponding gains are much larger - 152.3 and 154.3 percent respectively.

## 7. Conclusion

Missouri, like most other states, uses assessments in its accountability system that are intended to indicate whether students are on a pathway to "college and career readiness." The state longitudinal data system (SLDS) now has the capacity to assess directly the strength of the association between $8^{\text {th }}$-grade MAP scores in Communication Arts, Science, or Math and postsecondary educational attainment. Using data for four cohorts of high school freshman, we find a very strong association between $8^{\text {th }}$-grade MAP performance levels on each of the assessments and post-secondary degree completion, overall and by race/ethnic and gender groups. Odds ratios, commonly used in reporting biomedical findings, are a useful way to summarize the association between performance levels and post-secondary achievement. We find that a student scoring Proficient on any of the $8^{\text {th }}$ grade assessments is roughly twice as likely to earn a postsecondary degree and three times as likely to earn a four year degree as a student scoring Basic.

We used the SLDS data to estimate a student level model of educational attainment linking $8^{\text {th }}$-grade MAP performance levels and post-secondary attainment. Using this model, we simulated the effect of attaining the NCLB goal of 100 percent Proficient or higher for all students. We find that, if all Missouri students who currently score Below Basic and Basic are raised to Proficient, the number of 9th-grade students who earn post-secondary degrees would
increase by more than fifty percent. Black and Hispanic students, who start at much lower levels of MAP performance, have expected gains of 152 and 75 percent, respectively.

There is considerable controversy about the role of standardized tests in state accountability systems. Critics have argued that the tests are inadequate measures of school performance and may exhibit racial bias (e.g., Koretz, 2017; Jiminez and Mondaffari, 2021; Long, 2023). However, our examination of the Missouri experience finds that the NCLBmandated $8^{\text {th }}$-grade assessments are strongly associated with post-secondary educational attainment - overall and by subgroup. We also note that many students who do not reach Proficient attend college. For example, 37\% of all students who score Basic in Math attend college, with the highest percentages (45\%) for Black female and White female students. However, most of these students do not complete a degree. Thus, attainment of the NCLB goal of universal $8^{\text {th }}$-grade proficiency as measured by these assessments would improve degree completion rates not just by increasing college attendance, but also by increasing their degree completion rates once in college. Importantly, moving students to proficiency would produce exceptionally large gains for Black and Hispanic as compared to White students and thus considerably narrow post-secondary educational attainment gaps.

## No Child Left Behind (NCLB) Simulation

Logit Model:

$$
\operatorname{logit}\left(Y_{i}\right)=\ln \left(\frac{P\left(Y_{i}=1\right)}{1-P\left(Y_{i}=1\right)}\right)=\beta_{0}+\beta_{1}{M a t h P L_{i}}+\beta_{2} \text { SciencePL }_{i}+\beta_{3} C A P L_{i}+\beta_{4} F R L
$$

$P\left(Y_{i}=1\right)$ refers to the probability that student $i$ achieves the outcome, $Y_{i}$; Math, Science, and CA refer to the three MAP exams; PL refers to students' performance level on each MAP score (Below Basic; Basic; Proficient; Advanced). In this specification the omitted performance level for each test is Below Basic. Thus, $\beta_{0}$ represents the outcome for a student who scores Below Basic on all three assessments.
Samples: The model was estimated across all students and then by race-by-gender group. Because the models were estimated independently, each will have their own values for the goodness of fit tests.

## NCLB Simulation Goodness-of-Fit

For the following examination on each logit model's goodness of fit, we rely on the area under the Receiver Operating Characteristic (ROC) curve, often referred to as the concordance statistic (C-Statistic). The C-Statistic can also be interpreted as the proportion of pairs of individuals whose observed and predicted outcomes agree (i.e., are concordant) among all possible pairs in which one individual experiences the outcome of interest and compares their predicted values to all individuals who did not experience the outcome. Values range from 0 to 1 and the closer to one, the more concordance and the better fit.

Table 8. NCLB Simulation Logit Goodness of Fit: C-Statistics

|  | Group | C-Statistic |
| :--- | :--- | :---: |
| AttenCol_5Y | BF | 0.678 |
|  | BM | 0.691 |
|  | HM | 0.719 |

[^6]
[^0]:    ${ }^{1}$ For a recent survey see Chingos and Furtado (2024).

[^1]:    2 "Student performance on the total test can be reported in terms of four performance levels that describe a pathway to proficiency and college and career readiness. Each performance level represents standards of performance for English Language Arts, Mathematics, and Science. Panels drawn from education, business, and professional communities determined the performance standards." (Emphasis added) https://dese.mo.gov/media/pdf/map-grade-level-assessment-spring-2023-guide-interpreting-results

[^2]:    ${ }^{3} \mathrm{https}: / / \mathrm{www}$. studentclearinghouse.org/about/how-we-serve-the-k-20-to-workforce-continuum/
    ${ }^{4}$ Communication Arts has since been renamed as English Language Arts

[^3]:    ${ }^{5}$ To simplify exposition, we have suppressed information on standard errors in the text. In the Appendix we report standard errors for all of the statistics reported in the text. In the example above, the odds ratio for Communication Arts is significantly larger than the similar odds ratio for Math or Science.

[^4]:    ${ }^{6}$ Given the small cell sizes for some of the groups, it was not possible to reliably estimate the odds ratio for Advanced versus Below Basic reported earlier for all students.
